

How many dB does the optical module output

Overview

optimal operating range: from -10 to -25 dBm (depending on the equipment). Important! A signal that is too strong (typically above +3 dBm) can overload the optical receiver. While dBm is the actual power level represented in milliwatts, dB (decibel) is the difference between the powers. A decibel is expressed as the base 10 logarithm of the ratio of the power of two signals, as shown here: $10 \times \lg(P_1/P_2)$ is the base 10 logarithm, and P_1 and P_2 are the powers to be compared. They can be converted as follows: $\text{dBm} = 10 \times \lg(P)$. Here, P indicates optical power, in mW. This illustrates how dB and dBm work together within the same transmission system. A simplified power budget relationship can be expressed as: Available Power. The receiving power range of the optical module primarily depends on Module Type □ Transmission Rate And Transmission distance Generally speaking, The multi-mode optical module has a receiving power range of -20 dBm to 0 dBm.
