

Working principle of needle fiber optic sensor

Overview

Radiation absorption creates electronic excited states that are trapped by localized defects for extended periods of time. This work reviews the fiber-optic sensors based on Bragg gratings, long period gratings, interferometers, surface plasmon resonance, fluorescence, and light scattering. Brief theory of sensing principle, fabrication method, applications, advantages and disadvantages of the different fiber-optic. Radiation absorption excites an orbital electron to a higher energy level. It's a device that converts light rays into electronic signals. The distributed measurement is achieved by the interrogator which detects the light scattered from each section of the fiber. Biopsy needles with embedded force sensors can eliminate the needle deflection and the needle targeting failure risks during MRI guided biopsy procedures.
